

Conservation Law Foundation  
Docket No. 5330  
Exhibit CLF-PLC-1

STATE OF VERMONT  
PUBLIC SERVICE BOARD

DIRECT TESTIMONY OF

PAUL CHERNICK  
PLC, Inc.

ON BEHALF OF THE

CONSERVATION LAW FOUNDATION OF NEW ENGLAND  
VERMONT PUBLIC INTEREST RESEARCH GROUP  
VERMONT NATURAL RESOURCE COUNCIL

December 19, 1989

1

2 Q: Mr. Chernick, please state your name, occupation and business  
3 address.

4 A: My name is Paul L. Chernick. I am President of PLC, Inc., 18  
5 Tremont Street, Suite 703, Boston, Massachusetts.

6 Q: Mr. Chernick, would you please briefly summarize your  
7 professional education and experience?

8 A: I received a S.B. degree from the Massachusetts Institute of  
9 Technology in June, 1974 from the Civil Engineering Department,  
10 and a S.M. degree from the Massachusetts Institute of  
11 Technology in February, 1978 in Technology and Policy. I have  
12 been elected to membership in the civil engineering honorary  
13 society Chi Epsilon, and the engineering honor society Tau Beta  
14 Pi, and to associate membership in the research honorary  
15 society Sigma Xi.

16 I was a Utility Analyst for the Massachusetts Attorney  
17 General for over three years, and was involved in numerous  
18 aspects of utility rate design, costing, load forecasting, and  
19 the evaluation of power supply options.

20 As a Research Associate at Analysis and Inference, and in  
21 my current position, I have advised a variety of clients on  
22 utility matters. My work has considered, among other things,  
23 the need for, cost of, and cost-effectiveness of prospective  
24 new generation plants and transmission lines; retrospective  
25 review of generation planning decisions; ratemaking for plant  
26 under construction; ratemaking for excess and/or uneconomical  
27 plant entering service; conservation program design; cost

1 recovery for utility efficiency programs; and the valuation of  
2 environmental externalities from energy production and use.

3 My resume is attached to this testimony as Exhibit CLF-PLC-2.

4 Q: Mr. Chernick, have you testified previously in utility  
5 proceedings?

6 A: Yes. I have testified approximately sixty times on utility  
7 issues before various regulatory, legislative, and judicial  
8 bodies, including the Massachusetts Department of Public  
9 Utilities, the Massachusetts Energy Facilities Siting Council,  
10 the Illinois Commerce Commission, the Texas Public Utilities  
11 Commission, the New Mexico Public Service Commission, the  
12 District of Columbia Public Service Commission, the New  
13 Hampshire Public Utilities Commission, the Connecticut  
14 Department of Public Utility Control, the Michigan Public  
15 Service Commission, the Maine Public Utilities Commission, the  
16 Minnesota Public Utilities Commission, the Federal Energy  
17 Regulatory Commission, and the Atomic Safety and Licensing  
18 Board of the U.S. Nuclear Regulatory Commission. A detailed  
19 list of my previous testimony is contained in my resume.  
20 Subjects I have testified on include nuclear power plant  
21 construction costs and schedules, nuclear power plant operating  
22 costs, power plant phase-in procedures, the funding of nuclear  
23 decommissioning, cost allocation, rate design, long range  
24 energy and demand forecasts, utility supply planning decisions,  
25 conservation costs and potential effectiveness, generation

1 system reliability, fuel efficiency standards, and ratemaking  
2 for utility production investments and conservation programs.

3 Q: Have you testified previously before this Board?

4 A: Yes. I testified three times before the Board. The two most  
5 recent occasions were in Docket 5270, first on behalf of the  
6 Conservation Law Foundation (CLF) and second on behalf of the  
7 Central Vermont Public Service (CVPS) conservation  
8 collaborative.<sup>1</sup>

9 Q: Have you been involved in utility resource planning in Vermont?

10 A: Yes. I have been a consultant to the CVPS collaborative with  
11 CLF and the DPS since late 1988. None of the information  
12 presented in this testimony comes from the collaborative  
13 effort, other than material in public documents.

14 Q: Have you authored any publications on utility ratemaking  
15 issues?

16 A: Yes. I have authored a number of publications on rate design,  
17 cost allocations, power plant cost recovery, conservation  
18 program design and cost-benefit analysis, and other ratemaking  
19 issues. These publications are listed in my resume.

20 Q: What is the purpose of this testimony?

21 A: The purpose of this testimony is to review the connection  
22 between energy efficiency programs and the proposed purchase  
23 of Hydro-Quebec power (the HQ purchase) and energy by the 24  
24 Vermont utilities (the Participants).

---

25 <sup>1</sup>Part of the latter testimony reflected the opinion of CLF  
26 (as well as the other intervenors) and of CVPS, but not the  
27 Department of Public Service (DPS).

1 Q: How is the purchase related to utility-sponsored energy  
2 efficiency programs?

3 A: To some extent, any two utility resources are potential  
4 competitors. Specifically, if the Participants included all  
5 cost-effective conservation in their resource plans, the need  
6 for and economics of the HQ purchase would be much less  
7 compelling. Conversely, once the Participants are committed  
8 to the HQ purchase, the amount of cost-effective energy  
9 efficiency potential will be reduced. Thus, a premature  
10 commitment to the HQ purchase could result in higher costs to  
11 Vermont ratepayers in the long run, even if the HQ purchase is  
12 less expensive than the Participants' supply alternatives.

13 Q: If the HQ purchase is less expensive than other supply options,  
14 does that necessarily imply that it is the most economical  
15 resource?

16 A: No. Efficiency investment may be even less expensive than the  
17 HQ purchase.

18 Q: If efficiency is less expensive than the HQ purchase, will it  
19 not be able to displace the HQ purchase, even once a contract  
20 is signed?

21 A: Not necessarily. The total cost of the HQ purchase is fairly  
22 high; it is my understanding that the contract is designed to  
23 be slightly less expensive than a new coal plant. Large  
24 efficiency investments are economical at lower costs than the  
25 cost of the HQ purchase. However, efficiency which is less  
26 expensive than the total purchase cost may not be cost-

1 effective once the HQ contract is signed. A large fraction  
2 (and perhaps all) of the total purchase cost is recovered  
3 through fixed charges, consisting of demand charges and take-  
4 or-pay energy charges. Most efficiency investments will have  
5 a difficult time competing with a resource whose marginal cost  
6 is zero.

7 Q: Even after the Participants become committed to the HQ  
8 purchase, if they do, would there not be other supply resources  
9 which conservation could back out?

10 A: There certainly would be some resource which efficiency  
11 investments could back out. However, it appears that locking  
12 in the proposed purchase would greatly reduce the amount of  
13 cost-effective energy efficiency investment. Only a small  
14 fraction of the energy in Vermont's supply mix would have high  
15 avoidable costs. Some conservation measures are so inexpensive  
16 that they are cost-effective, even if their only effect on  
17 power supply is that they allow the utility to avoid the fuel  
18 costs of a nuclear plant. However, the amount which is cost-  
19 effective at that low avoided cost is much less than the amount  
20 which is cost-effective for avoiding a higher-priced fuels  
21 (such as oil), or the entire cost of a long-term purchase (such  
22 as the HQ contract). Since the cost of the HQ contract is  
23 largely unavoidable once the contract is approved, the energy  
24 cost avoidable by efficiency investment would fall to the price  
25 of the remaining fuels.

1 Q: Could the Participants resell the HQ energy for a profit to  
2 other utilities?

3 A: The Participants are likely to be able to resell the energy at  
4 a price higher than the energy charges. However, this price  
5 would generally reflect a split in savings between the buyer  
6 and seller. Since the variable cost of the resale would be  
7 very low, the price will usually be much lower than the cost  
8 of the buyer's avoided energy cost. The amount received by the  
9 Participants would also often be reduced by the cost of  
10 transmission charges.

11 For example, consider the resale of economy energy from  
12 Schedule B in 1997 to a utility displacing 1% sulphur #6 oil,  
13 a common marginal fuel in New England. Assuming a capacity  
14 charge of \$319/kW (\$1225 in 1985 dollars, plus 10 years of  
15 Handy-Whitman inflation at 5% to 1995, times a 16% carrying  
16 charge) and a 75% capacity factor, the capacity charge per kWh  
17 will be 4.9 cents.<sup>2</sup> Escalating the 1.774 cent/kWh energy  
18 charge at 4% CPI inflation for 12 years to 1997 produces an  
19 energy charge of 3.2 cents/kWh. The total cost of the purchase  
20 is thus 8.1 cents/kWh. DRI's Fall 1989 oil price projection  
21 gives a 1997 price for 1% sulphur #6 oil of \$4.77/MMBTU; at a  
22 fairly poor heat rate of 11,000 BTU/kWh, this is equivalent to  
23 5.25 cents/kWh. Assuming a split-savings agreement, the  
24 revenue to the Participant would be 4.2 cents, or barely more

---

25 <sup>2</sup>With a real-levelized carrying charge, this would be more  
26 like 3.6 cents/kWh.

1 than half of the cost of the HQ purchase,<sup>3</sup> and about 80% of the  
2 avoided fuel cost. If the Participant must pay (or absorb) a  
3 wheeling charge of 2 mills, the net revenue would be 4 cents.

4 Thus, the price that the Participants are likely to be able  
5 to negotiate for the resale of HQ energy to other utilities is  
6 likely to be well below the total cost of the purchase. While  
7 such resale would moderate the net cost of purchasing too much  
8 power from Hydro-Quebec, it would not provide a very strong  
9 incentive for energy efficiency investments.

10 Q: How large might the potential be for cost-effective electricity  
11 conservation in Vermont?

12 A: No precise answer to that question is currently available. The  
13 amount of cost-effective conservation depends on the social  
14 avoided cost (including externalities and risk reduction), on  
15 the composition of current and future stocks of buildings and  
16 equipment, on the evolution of efficient technologies, and  
17 other factors. No comprehensive study of conservation  
18 potential has been performed for Vermont. However, we can get  
19 a rough sense of the potential by examining the results of  
20 studies performed in other states. It should be noted that  
21 these studies generally reflect technology options from several  
22 years ago: the cost of efficiency improvements have fallen,  
23 and potential has increased. The values of avoided costs used  
24 in these analyses vary, but they generally represent some proxy

---

25 <sup>3</sup>The revenue would be about 62% of the total cost if the  
26 capacity charge were real-levelized.

1 for new baseload plant construction, without any adjustment for  
2 risk or externalities.<sup>4</sup> Also, these studies generally do not  
3 examine fuel-switching from electricity to direct fuel use,  
4 which my work for the Boston Gas Company has indicated is  
5 highly cost-effective, both in terms of direct costs and in  
6 terms of total social costs, including externalities.

7 Chernick, et al. (1989), a study prepared for the Minnesota  
8 Department of Public Service, determined that the total cost-  
9 effective conservation potential for Minnesota's electric  
10 utilities was 52%. We estimated that potential cost-effective  
11 efficiency savings were 60% in the residential class, 50% for  
12 farms, 60% for commercial customers, and 35% in industry.

13 Power to Spare (New England Energy Policy Council, 1987)  
14 estimated that technologies which were then commercially  
15 available could reduce Vermont electric energy requirements by  
16 35% by the year 2005, compared to utility forecasts which  
17 included their projections of efficiency improvements. With  
18 "potentially available" technology, which included technologies  
19 judged likely to be available in the forecast period, the  
20 potential reduction in usage by 2005 rose to 57%.

21 Lovins (1986a) estimated a 50% cost-effective potential  
22 savings in energy use of the 1984 building and equipment stock  
23 in Ontario. In the industrial sector, 70% savings were

---

24 <sup>4</sup>Except for the PLC, Inc. (1989) study, and Lovins's work,  
25 (1986a, 1986b) these analyses generally ignore avoided line losses  
26 and avoided transmission and distribution costs. Krause, et al.,  
27 (1988) use an avoided cost which only reflects the utilities' fuel  
28 costs.

1 possible, in the commercial sector 32% savings, and in the  
2 residential sector, 46% savings.

3 Lovins (1986b), a report to the Austin (TX) Electric  
4 Utility Department, found that cost-effective efficiency  
5 investment by 2005 could reduce annual peak demand by 73%, and  
6 energy usage by 72%.

7 Usibelli, et al., (1983), a study commissioned by DOE,  
8 found that technically feasible energy conservation measures  
9 costing less than 40 mills (roughly equal to the Northwest  
10 Power Planning Council's estimate of avoided supply costs)  
11 could reduce residential electricity demand in 2000 by 36.5%  
12 in the Pacific Northwest.

13 Geller, et al., (1986), prepared for Pacific Gas and  
14 Electric, examined seven end-uses representing 70% of PG&E's  
15 residential electricity consumption. They found that cost-  
16 effective efficiency investment could reduce electric energy  
17 needs in 2005 by 25%-44%, depending on the penetration of  
18 current and prototype technologies.

19 Miller, et al., (1989), a draft study for the New York  
20 State Energy Research and Development Authority, estimated that  
21 efficiency investments in the 1986 building stock which were  
22 cost-effective under their "societal" test, would yield 34%  
23 savings in the residential class, 46% reduction in commercial  
24 electric usage, and 17% savings in the industrial class, for  
25 a total savings of 34%.

1 California Energy Commission (1984) limited its scope to  
2 retrofit technology and capability for office and retail  
3 buildings built before 1983. That study concluded that full  
4 implementation of cost-effective measures, with pay-back  
5 periods of one to three years, would reduce the electrical  
6 usage in those buildings by 36%.

7 Krause et al., (1988) studied the residential loads of  
8 Michigan's two largest utilities, and estimated conservation  
9 potential from existing and prototype technologies at 42% of  
10 usage in 1995 and 56% in 2005, if those measures were pursued  
11 aggressively.

12 Overall, it seems reasonable to expect cost-effective  
13 energy efficiency potential in the 30-70% range, depending on  
14 the level of avoided costs, the time frame used, and other  
15 variables.

16 Q: How much of Vermont's energy supply is expected to be provided  
17 by power sources which have low avoidable costs?

18 A: The DPS's forecast of Vermont electric energy requirements in  
19 the 1988 Twenty Year Electric Plan for the year 2000 is  
20 approximately 6.3 terawatthours (TWH, or billions of kWh).  
21 Load growth has been somewhat higher than might have been  
22 expected from the 1984 data used in the Twenty Year Plan, so  
23 I will assume that energy requirements at the turn of the  
24 century would be about 10% higher than the Plan's estimate, or  
25 6.9 TWH. Existing and committed sources (using DPS

1 assumptions, where available) at the end of the century with  
2 low variable costs include:

- 3
- 4 ● Vermont Yankee (286 MW at 69% capacity factor): 1.8 TWH,
- 5
- 6 ● Other New England nuclear entitlements (64 MW at 65%
- 7 capacity factor): 0.4 TWH,
- 8
- 9 ● Vermont hydro: about 0.5 TWH, and
- 10
- 11 ● Small Power Producers: 0.9 TWH,
- 12

13 for a total of 3.6 TWH. Some of the thermal small power  
14 producers may be dispatchable, with significant variable costs,  
15 but the 0.9 TWH includes only the DPS's estimate of small power  
16 committed by 1987, and excludes any contracts signed since  
17 then.<sup>5</sup> On the other hand, some of the small power projects may  
18 not be completed. With these uncertainties, roughly 3.3 TWH  
19 of energy for the year 2000 would be supplied with existing  
20 high-fuel-cost sources or with sources yet to be committed.

21 Q: Is the HQ purchase large enough to affect the amount of cost-  
22 effective electric conservation in Vermont?

23 A: Yes. The HQ contract would supply about 3.0 TWH of energy from  
24 2001-2011, and over 2.2 TWH from 1996-2015. If the  
25 Participants exercised their maximum cancellations, the energy  
26 deliveries would be 2.2 TWH from 1996-2011, and over 1.4 TWh  
27 through 2015. However, most of the cancellations would have  
28 to be elected by 4/91 and 11/92. The Participants will have  
29 to act very quickly if they are to have significantly better

---

30 <sup>5</sup>The DPS 20-year plan is now over a year old, and some of this  
31 data may be slightly stale. In addition, I have supplied estimates  
32 for some of the values, such as in-state hydro generation. I  
33 intend for the values to be indicative, rather than definitive.

1 to act very quickly if they are to have significantly better  
2 information about efficiency opportunities by 1992 than they  
3 do today. If those early cancellations are not exercised, but  
4 all of the later cancellations are exercised, the 2001-2011  
5 purchase level would be 2.7 TWH. I will treat this as the  
6 base-case purchase level.

7 The combination of HQ with existing and committed sources  
8 would essentially fulfill Vermont's energy needs into the next  
9 century.<sup>6</sup> Of the output of 6.9 TWH, roughly 6.3 TWH would be  
10 served by the sources with locked-in costs, leaving only 0.6  
11 TWH, or less than 9% of energy requirements at the turn of the  
12 century to be provided by high-fuel-cost or new supplies.  
13 Thus, aggressive efficiency programs would rapidly run out of  
14 displaceable energy supplies.<sup>7</sup>

15 Q: How long would this condition persist?

16 A: With load growth of 2% annually, output requirements would  
17 reach 7.7 TWH by 2005, opening some room for efficiency  
18 investment. Still, only about 1.4 TWH (or 18% of output) would  
19 be displaceable over the 15 year period from 1990-2005. Only  
20 with the retirement of Vermont Yankee, currently scheduled for

---

21 <sup>6</sup>In the 1996-98 period, with most of the HQ purchase in place  
22 and the Merrimack purchase still in effect, the situation would be  
23 even more extreme.

24 <sup>7</sup>I have performed this analysis on a statewide basis. The  
25 results for individual utilities will differ. CVPS, for example,  
26 represents a larger portion of Vermont energy sales (about 55%)  
27 than it does of the HQ purchase (about 40%), so it would be less  
28 affected than would the average utility.

1           2007,<sup>8</sup> would a significant amount of Vermont's energy supply be  
2           displaceable by efficiency investments.

3           Q: What changes in the HQ contract would mitigate the problems you  
4           have identified?

5           A: The adverse effect of the HQ purchase on cost-effective  
6           conservation could be mitigated through any of several changes  
7           in the contract, or a combination of such changes.

8           First, the scale of the purchase could be reduced. If the  
9           purchase were one third the proposed size (about 1 TWH), 2.3  
10          TWH (or 33%) of energy output in the year 2000 could be  
11          displaced by efficiency investment.<sup>9</sup> By the year 2005, the  
12          displaceable energy would rise to 3.1 TWH, or 40% of output.  
13          While these values are at the low end of the likely range of  
14          cost-effective efficiency improvements, they provide  
15          substantial opportunities for efficiency investment, and  
16          roughly triple the scale of programs which would be cost-  
17          effective, compared to the base case.

---

18           <sup>8</sup>This date is subject to change in either direction. Early  
19           unplanned retirement of Vermont Yankee (or any other nuclear unit)  
20           is a distinct possibility. This would not provide much opportunity  
21           for coordination with efficiency programs. Planned early  
22           retirement would be more advantageous. Vermont Yankee may also  
23           attempt to extend the life of the plant; that decision may or may  
24           not be subject to review by the PSB. The NRC is currently  
25           formulating rules for the extension of nuclear plant operating  
26           licenses by 20 years, which would take Vermont Yankee to 2027.  
27           Even without those "life-extension" rules, Vermont Yankee may be  
28           able to extend its operating license to 2011, 40 years after it  
29           received its operating license.

30           <sup>9</sup>A 50-MW QF contract, for example, would be much less  
31           problematic in this regard than the proposed HQ contract.

1           Second, shortening the length of the purchase would reduce  
2           its interference with energy efficiency investments. Purchases  
3           in the next few years would tend to have less effect on the  
4           economics of efficiency improvements than would later  
5           purchases. Since utility efficiency programs can only ramp up  
6           at limited rates, reductions of 20-30% are unlikely until late  
7           in the decade.

8           Third, adding provisions which would allow the Participants  
9           to back out of portions of the HQ purchase, even after the  
10          schedules have started, would reduce or eliminate the conflict  
11          between the purchase and energy efficiency. If the  
12          Participants could reduce their take of the purchase under a  
13          reasonably flexible set of circumstances (e.g., on a few years'  
14          notice, and if efficiency programs reduce sales by specified  
15          amounts), efficiency could back out the HQ purchase, just as  
16          it could back out new generation sources, existing oil, or  
17          other high-variable-cost supplies.

18          Fourth, redesigning the rates and the take-or-pay  
19          obligation would reduce the conflict between the HQ purchase  
20          and energy efficiency. If the demand charge were a small part  
21          of the purchase cost, and if the energy charges were all  
22          avoidable, efficiency would continue to have a fair opportunity  
23          to compete with the HQ purchase.

24          In summary, the proposed HQ purchase is problematical due  
25          to its large size, its extensive length, its inflexibility, and  
26          its low variable cost. Correcting some combination of these

1 problems would allow Vermont utilities to aggressively pursue  
2 efficiency opportunities, which are likely to be more  
3 economical for ratepayers in the long run than the full HQ  
4 contract.

5 Q: Given these options for mitigation of the contract, do you have  
6 any specific recommendations for the Board regarding the  
7 disposition of Participants' petition?

8 A: No. I have not performed the analysis necessary to determine  
9 what combination of these fixes to the purchase contract would  
10 be most advantageous to Vermont, nor to determine what  
11 combination would be most acceptable to Hydro-Quebec. Before  
12 the Board approves any purchase from HQ, it should require the  
13 Participants to demonstrate that changes in the contract terms  
14 have mitigated the conflict with efficiency investments.

15 Q: If the Board were faced with a choice between the entire HQ  
16 purchase as proposed, or with no purchase from HQ, without any  
17 opportunity for mitigation, what action would you advise?

18 A: I have not reached a definitive conclusion on that matter.  
19 Given a choice of the entire HQ purchase as proposed (without  
20 any of the mitigation measures discussed above), or a major  
21 efficiency program without any new long-term HQ purchases, the  
22 efficiency option is likely to be preferable, in terms of  
23 expected cost, environmental benefits, and risk mitigation.  
24 In the absence of a formal Vermont-specific comparison of the  
25 HQ purchase to efficiency investments, I would recommend that  
26 the Board carefully consider (and heavily weight) the magnitude

1 of the efficiency resource it would be jeopardizing if it  
2 allowed the HQ contract to go into effect as proposed.

3 Q: Does this conclude your testimony?

4 A: Yes.
